6	Indices and tables	29	

The STIX Validator checks that STIX JSON content conforms to the requirements specified in the latest STIX 2 specifications. In addition to checking conformance with the JSON schemas, the validator checks conformance with requirements that cannot be specified in JSON schema, as well as with established "best practices." This validator is non-normative; in cases of conflict with the STIX specification, the specification takes precedence.

The STIX 2 specification contains two types of requirements: mandatory "MUST" requirements, and recommended "SHOULD" best practice requirements. The validator checks documents against the "MUST" requirements using JSON schemas. Some of these mandatory requirements cannot be implemented in JSON Schema, however, so the validator uses Python functions to check them. The "SHOULD" requirements are all checked by Python functions, and options may be used to ignore some or all of these recommended "best practices."

The STIX Validator uses the stix2-patterns validator to check that Indicator patterns conform to the STIX Patterning language and only reference properties valid for the objects in the pattern.

The validator also color-codes its output to make it easier to tell at a glance whether validation passed.

#### Installation

Note: The STIX 2 validator requires Python 2.7 or 3.4+.

The easiest way to install the STIX 2 validator is with pip:

```
$ pip install stix2-validator
```

Note that if you instead install it by cloning or downloading the repository, you will need to set up the submodules before you install it:

```
$ git clone https://github.com/oasis-open/cti-stix-validator.git
$ cd cti-stix-validator/
$ git submodule update --init --recursive
$ python setup.py install
```

#### Usage

#### 2.1 As A Script

The validator comes with a bundled script which you can use to validate a JSON file containing STIX content:

```
$ stix2_validator <stix_file.json>
```

#### 2.2 As A Library

You can also use this library to integrate STIX validation into your own tools. You can validate a JSON file:

```
from stix2validator import validate_file, print_results
results = validate_file("stix_file.json")
print_results(results)
```

You can also validate a JSON string, and check if the input passed validation:

```
from stix2validator import validate_string, print_results
stix_json_string = "..."
results = validate_string(stix_json_string)
if results.is_valid:
    print_results(results)
```

If your STIX is already in a Python dictionary (for example if you have already run json.loads()), use validate\_instance() instead:

```
import json
from stix2validator import validate_instance, print_results
```

(continues on next page)

(continued from previous page)

```
stix_json_string = "..."
stix_obj = json.loads(stix_json_string)
results = validate_instance(stix_obj)
if results.is_valid:
    print_results(results)
```

You can pass a ValidationOptions object into validate\_file(), validate\_string(), or validate\_instance() if you want behavior other than the default:

```
from stix2validator import ValidationOptions
options = ValidationOptions(strict=True)
results = validate_string(stix_json_string, options)
```

#### 2.3 STIX 2 Versions

By default the validator will check content against the latest version of the STIX 2 specification. However, older versions can be checked with the version option. For example:

\$ stix2\_validator --version=2.0 <stix\_file.json>

or in Python:

```
options = ValidationOptions(strict=True, version="2.0")
results = validate_string(stix_json_string, options)
```

#### 2.4 Additional Schemas

The validator uses the STIX 2 JSON schemas as the basis for its validation, but you can also validate with your own additional schemas. This can help if you want to validate STIX content using extensions or (now deprecated) custom objects, properties, or observables.

To do this use the --schemas argument:

\$ stix2\_validator --schemas /path/to/my/schemas <stix\_file.json>

or in Python, using schema\_dir:

You can see some examples of custom schemas here.

Note: The schema's filename must match the extension definition id of the extension it describes so the validator can apply it correctly. For example, a schema defining a new extension with an id of

extension-definition--bfaece0b-efa6-4dfa-8248-3d340e2030f8 should be named *extension-definition-bfaece0b-efa6-4dfa-8248-3d340e2030f8.json*.

**Note:** Custom objects and properties using the  $x_a$  and  $x_b$  prefixes have been deprecated in STIX 2.1. However, if you need a schema for validating them, the validator can parse it as long as the schema's filename matches the type name of the STIX object type it should apply to. For example, a schema defining a new property on Indicators should be named indicator.json. A schema defining a new object type, "my-cool-thing", would need to be named my-cool-thing.json.

**Note:** When using additional schemas, the validator's built-in schemas are still checked against. Thus custom schemas only need to contain the properties that differ from the standard.

# chapter $\mathbf{3}$

## Options

These are the different options that can be set, whether the validator is used as a command-line script or as a Python library. When using the validator as a library, these options can be passed as parameters to the ValidationOptions constructor.

Script	Library	Description
FILES	files	A whitespace separated list of STIX files or directories of STIX files to
		validate.
-r,recursive		Recursively descend into input directories.
-s SCHEMA_DIR,	schema_	Gustom schema directory. If provided, input will be validated against
schemas		these schemas in addition to the STIX schemas bundled with this script.
SCHEMA_DIR		
version	version	
-v,verbose	verbose	Print informational notes and more verbose error messages.
-q,silent	silent	Silence all output to stdout.
-d DISABLED,	disable	A comma-separated list of recommended best practice checks to skip.
disable		By default, no checks are disabled. Example: -disable 202,210
DISABLED,ignore		
DISABLED		
-e ENABLED,	enabled	1 1
enable ENABLED,		If the –disable option is not used, no other checks will be run. By default,
select ENABLED		all checks are enabled. Example: -enable 218
strict	strict	Treat warnings as errors and fail validation if any are found.
strict-types	strict_t	Expressere that no custom object types are used, only those defined in the
		STIX specification.
strict-properties	strict_	Emparethatsno custom properties are used, only those defined in the
		STIX specification.
no-cache		e Disable the caching of external source values.
refresh-cache	refresh_	Elears the cache of external source values, then during validation down-
		loads them again.
clear-cache		a Chear the cache of external source values after validation.
enforce-refs	enforce	Fensions that all SDOs being referenced by SROs are contained within
		the same bundle.

For the list of checks that can be used with the "enabled" or "disabled" options, see the Best Practices page.

#### **Checking STIX Content**

The validator will always validate input against all of the mandatory "MUST" requirements from the spec. By default it will issue warnings if the input fails any of the "SHOULD" recommendations, but validation will still pass. To turn these "best practice" warnings into errors and cause validation to fail, use the --strict option with the command-line script, or create a ValidationOptions object with strict=True when using the library.

You cannot select which of the "MUST" requirement checks will be performed; all of them will always be performed. However, you may select which of the "SHOULD" checks to perform. Use the codes from the table below to enable or disable these checks. For example, to disable the checks for the report label and tool label vocabularies, use --disable 218,222 or disabled="218,222". All the other checks will still be performed. Conversely, to only check that custom property names adhere to the recommended format but not run any of the other "best practice" checks, use --enable 103 or enabled="103".

Enabling supersedes disabling. Simultaneously enabling and disabling the same check will result in the validator performing that check.

Some checks access Internet resources to determine valid values for certain properties. For instance, the 'mimetype' check accesses the IANA's list of registered MIME types. These web requests are cached to conserve bandwidth, will expire after one week, and are stored in a file called 'cache.sqlite' in the same directory the script is run from. The cache can be refreshed manually with the --refresh-cache or refresh\_cache=True, or cleared with --clear-cache or clear\_cache=True. This caching can be disabled entirely with --no-cache or no\_cache=True.

## 4.1 Mandatory Checks - STIX 2.1

Nam	e Ensures	Errors/Warnings
tamp	- timestamps contain sane months, days, hours, min- utes, seconds	<pre>'<property>': '<timestamp>' is not a valid timestamp: <message> '<object>': '<property>': '<timestamp>' is not a valid timestamp: <mes- sage=""> '<object>': '<extension>': '<property>': '<timestamp>' is not a valid timestamp: <message> '<object>': '<property>': '<embedded-property>' is not a valid timestamp: <message></message></embedded-property></property></object></message></timestamp></property></extension></object></mes-></timestamp></property></object></message></timestamp></property></pre>

#### Contributing

We're thrilled that you're interested in contributing to the stix2-validator! Here are some things you should know:

- contribution-guide.org has great ideas for contributing to any open-source project (not just this one).
- All contributors must sign a Contributor License Agreement. See CONTRIBUTING.md in the project repository for specifics.
- If you are planning to implement a major feature (vs. fixing a bug), please discuss with a project maintainer first to ensure you aren't duplicating the work of someone else, and that the feature is likely to be accepted.

Now, let's get started!

#### 5.1 Setting up a development environment

We recommend using a virtualenv.

1. Clone the repository. If you're planning to make pull request, you should fork the repository on GitHub and clone your fork instead of the main repo:

\$ git clone https://github.com/yourusername/cti-stix-validator.git

2. Install develoment-related dependencies and set up git submodules:

```
$ cd cti-stix-validator
$ pip install -r requirements.txt
$ git submodule update --init --recursive
$ git submodule foreach -q --recursive 'git switch $(git config -f $toplevel/.gitmodules submodule.$r
}
```

3. Install pre-commit git hooks:

```
$ pre-commit install
```

At this point you should be able to make changes to the code.

#### 5.2 Code style

All code should follow PEP 8. We allow for line lengths up to 160 characters, but any lines over 80 characters should be the exception rather than the rule. PEP 8 conformance will be tested automatically by Tox and Travis-CI (see below).

### 5.3 Testing

**Note:** All of the tools mentioned in this section are installed when you run pip install -r requirements. txt.

This project uses pytest for testing. We encourage the use of test-driven development (TDD), where you write (failing) tests that demonstrate a bug or proposed new feature before writing code that fixes the bug or implements the features. Any code contributions should come with new or updated tests.

To run the tests in your current Python environment, use the pytest command from the root project directory:

\$ pytest

This should show all of the tests that ran, along with their status.

You can run a specific test file by passing it on the command line:

\$ pytest stix2validator/test/test\_<xxx>.py

To ensure that the test you wrote is running, you can deliberately add an assert False statement at the beginning of the test. This is another benefit of TDD, since you should be able to see the test failing (and ensure it's being run) before making it pass.

tox allows you to test a package across multiple versions of Python. Setting up multiple Python environments is beyond the scope of this guide, but feel free to ask for help setting them up. Tox should be run from the root directory of the project:

\$ tox

We aim for high test coverage, using the coverage.py library. Though it's not an absolute requirement to maintain 100% coverage, all code contributions must be accompanied by tests. To run coverage and look for untested lines of code, run:

```
$ pytest --cov=stix2validator
$ coverage html
```

then look at the resulting report in htmlcov/index.html.

All commits pushed to the master branch or submitted as a pull request are tested with Travis-CI automatically.

### 5.4 Adding a dependency

One of the pre-commit hooks we use in our develoment environment enforces a consistent ordering to imports. If you need to add a new library as a dependency please add it to the *known\_third\_party* section of *.isort.cfg* to make sure the import is sorted correctly.

## 5.5 Updating the STIX JSON schemas

When updates have been made to the STIX JSON schemas repository, the schemas included in this library must also be updated. To do so:

\$ git submodule update --remote

Indices and tables

- genindex
- modindex
- search
